Magnetoelectric, magnetodielectric and magneto-impedance couplings in Bi$_{1-x}$Nd$_x$Fe$_{0.99}$Co$_{0.01}$O$_3$ compounds

Acoplamentos magnetoelétricos, magnetodielétricos e magnetoimpedância em compostos Bi$_{1-x}$Nd$_x$Fe$_{0.99}$Co$_{0.01}$O$_3$

Acoplamientos magnetoelectricos, magnetodiæliectricos y magneto-impedancia en compuestos Bi$_{1-x}$Nd$_x$Fe$_{0.99}$Co$_{0.01}$O$_3$

Abstract

In this work Bi$_{1-x}$Nd$_x$Fe$_{0.99}$Co$_{0.01}$O$_3$ ceramics compositions were synthesized for x = 0.05, 0.20 and, y = 0.01. Structural refinement results show that most of the samples crystallized in a rhombohedral symmetry with R3c. Measurements magnetoelectric coefficient, show that the magnetoelectric coefficients are of second order. The electrical impedance characterization of in function external magnetic fields, has a relative variation of the real dielectric response, the loss tangent and the electrical impedance. The systems, as the DC magnetic field strength increased a gain in both the values of the dielectric constant variation, as well as the variation of the electrical impedance. In other words, the greater the intensity of the magnetic field, the greater your response. There were also significant variations with of the magnetic field AC.

Keywords: Ceramics; BiFeO$_3$; Non-linear magnetoelectric effect.
Resumen
En este trabajo se sintetizaron composiciones cerámicas Bi$_1$ - xNd$_x$Fe$_{0.99}$Co$_{0.01}$O$_3$ para x = 0.05, 0.20 e, y = 0.01. Los resultados del refinamiento estructural muestran que la mayoría de las muestras cristalizaron en una simetría romboédrica con R3c. Las mediciones del coeficiente magnetoelectróico, muestran que los coeficientes magnetoelectricos son de segundo orden. La caracterización de impedancia eléctrica de campos magnéticos externos en función, tiene una variación relativa de la respuesta dieléctrica real, la tangente de pérdidas y la impedancia eléctrica. Los sistemas, a medida que la intensidad del campo magnético de DC aumentaron una ganancia tanto en los valores de la variación de la constante dieléctrica, como en la variación de la impedancia eléctrica. En otras palabras, cuanto mayor sea la intensidad del campo magnético, mayor será su respuesta. También hubo variaciones significativas con el campo magnético AC.

Palabras clave: Cerámica; BiFeO$_3$; Efecto magnetoelectróico no lineal.

1. Introducción

Materiales que simultaneaferrocioepropiedades, como magnetismo, ferroelectricidad y ferroelasticidad se clasifican como multiferroicos (Tokura, Seki & Nagosa 2014) (Ramazanoglu et al 2011). Las principales aplicaciones invierten estos materiales en sensores de prisma, sinpronic entre otros (Bilmes et al 2000) (Wang et al 2003). Bismuth ferrite es un multiferroico porque tiene dos órdenes ferroico siendo un magnetoeléctrico. Al promover material porque el ferroelectrico y magnetic room temperature, i.e. G-type antiferromagnetic order it has a transition of 640 K (T$_a$), while the ferroelectric order appears at about 1100 K (T$_C$). The BiFeO$_3$ crystallizes in a rhombohedral perovskite structure with R3c (Fiskei et al 1931). A of the problems shown by other authors is the appearance of unwanted phases in the process phase of bismuth ferrite (Hasan et al 2016). Some rare earth substitutions at the bismuth site (La$^3+$, Gd$^3+$, Tb$^3+$, Dy$^{3+}$) are reported by as an option to improve the electrical and magnetic properties of BiFeO$_3$ (Li et al 2013) (Fei et al 2015). A of the focus of this study is the dielectric measurements and impedances under action of an external magnetic field, classified as magnetodielectric and magnetoelectric respectively. These phenomena have resumed the great demand for magnetic field sensitive materials and their range of applications (Phan & Peng 2007). In this work, the Bi$_{1-x}$Nd$_x$Fe$_{0.99}$Co$_{0.01}$O$_3$ system was processed three samples thickness in the 1.2 mm and 5.4 mm diameter to make the characterizations.

2. Metodología

Este estudio se realizó en el laboratorio de ciencia materials and is part of a research on the development of electronic devices capable of electrical and magnetic interaction. The samples were processed under the following conditions: the precursors were weighed and mixed in three stoichiometry. Then were then through a high energy ball milling at 250 rotation per minute (RPM) for one hour. All samples were pressed and baked for sintering at 890° degrees for 3 minutes with rapid heating and cooling, called quenting (Shvartsman et al 2007). To check if the samples are in proper phases, X-ray diffraction was performed with Shimadzu diffractometer model XRD-7000, with scan rate of 2°/min, from 10° to 130°, in continuous mode at room temperature. From the x-ray diffraction, the refinement was performed using the Le Bail method, finding its network parameters. For dielectric measurements and electrical impedance under the magnetic field, an LCR meter (model E4980A), agilent function generator (model 33210A) and magnetic system (model GMW 5970-80) as shown in the measurement diagram of Figure 1.

The magnetodielectric and magnetoelectric measurements can be defined as $MD = \left(\frac{\varepsilon(H) - \varepsilon(0)}{\varepsilon(0)}\right)\times 100\%$ and $MI = \left(\frac{Z(H) - Z(0)}{Z(0)}\right)\times 100\%$ respectively.

2
3. Results and Discussion

The results on x-ray diffraction and Le Bail refinement of Figure 2 showed results with the same phase described in the literature (Mincach et al. 2016). According to the results of Le Bail refinement has the network parameters changing according to the doping. The sample volume a) has the larger volume then as neodymium increase the volume decreases, thus resulting in a phase change, noting also that noting also that $\chi^2$ in c) is above a good refinement. in c) is above a good refinement as show a Table 1. Analyzing each diffractogram can see a change in peaks between angles of 31° to 33° degrees. It is possible that a structural change is taking place in the systems phase as already reported in other work (Singh et al. 2017). The phase changes are happening in b) and c) of Figure 2, recent work (Oliveira 2015) has shown that these phases are rhombohedral and orthorhombic.

It can be seen from the magnetization (Figure 3) result that the compartment between the two samples is significant when we add more neodymium sample with 20 percent becomes almost paramagnetic. A possible explanation for this phenomenon may be lone pair moving from its center of symmetry (Geng et al. 2014), in which case the neodymium may be interfering with the magnetization of the system.

Figure 3: Magnetization curves at ambient temperature of samples Bi$_{0.95}$Nd$_{0.5}$Fe$_{0.99}$Co$_{0.01}$O$_3$, Bi$_{0.80}$Nd$_{0.2}$Fe$_{0.99}$Co$_{0.01}$O$_3$.

When a magnetic field is placed under a sample and its response with an electric voltage coefficient, it says that the material has a coupling between electricity and magnetism, so the material is magnetolectric as shown in Figure 4. The compartment of the two samples is observed to have similar shapes. The value of the magnetolectric coefficient is low and becomes lower when we add more neodymium. A possible explanation for this effect is that the values of electrostriction and magnetostriction (Shen et al. 2013) are not acting on the system in a linear way, but something more complex, such as the non-linear magnetolectric effect as reported in the works (Pirc & Blinc 2010).

The magnetodielectric measurement is a dielectric constant as a function of the external magnetic field. $\Delta\varepsilon'$ is the variation of the dielectric constant, $H_{\text{DC}}$ is the magnetic field between 1100 Oe and 8030 Oe plus the variation of the electric frequency $f_E$ 100, 500 and 1000 kHz as show a Figure 5. Analyzing the graphs and even with a low response exhibit a variation in the dielectric constant when increasing the DC magnetic field. This happens for a) and b). For sample with Bi$_{0.80}$Nd$_{0.2}$Fe$_{0.99}$Co$_{0.01}$O$_3$ has a small increase, certainly the neodymium is influencing the electrical properties of the system. This phenomenon can be seen in the paper (Rana et al 2019) (Basu et al 2019) which shows the variation of the dielectric constant under a magnetic field.

Figure 5: Variation of the dielectric constant under the applied magnetic field a) Bi$_{0.95}$Nd$_{0.5}$Fe$_{0.99}$Co$_{0.01}$O$_3$ with magnetic field DC 1100 Oe and 8030 Oe and b) Bi$_{0.80}$Nd$_{0.2}$Fe$_{0.99}$Co$_{0.01}$O$_3$ with magnetic field DC 1100 Oe and 8030 Oe.

The electrical impedance measurements follow the same scheme as the magnetodielectric measurement (Figure 6).

Analyzing the graphs, even having a low response, the variation of the electrical impedance happens when the DC magnetic field increases. The difference between the two samples is at the beginning of the measurement, in sample a) it starts with a value and decreases with the increase of the electric frequency. b) starts at zero and constantly increases with increasing magnetic field DC (Kammouni et al 2016) (Chizhik et al 2017). Indeed, when a magnetic field is under sample it responds with the change in electrical impedance (Li, Kavaldzhiev & Kosel 2015) (Liu et al 2012).

4. Conclusion

With the results of x-ray diffraction and refinement observed in the sample with 5% of neodymium a phase R3c. In the second sample with 20% neodymium it is possible that its structure is changing to another phase, possibly orthorhombic. and when we add more neodymium to the system it becomes more paramagnetic. Magnetoelectric results possibly show a nonlinear effect. Regarding the magnetodielectric and magneto-impedance measurements it can be observed that their nominal values increase when the DC magnetic field is increased, however this happens with the addition of neodymium.
